1. INTRODUCTION

The theory of network calculus has been developed since about 1990 to give a deterministic methodology for a worst-case evaluation of packet networks [7, 16, 2, 5]. It allows us estimating the end-to-end backlog and delay bounds, and it has been used to calculate the end-to-end quality-of-service guarantees. A merit of the network calculus is in its extendability where performance bound formulas for a single node can be easily extended to those for the end-to-end links by using min-plus algebra. More definitely, if we let $S_i(t)$ be a service curve, or a service guarantee, at node $i$ along the route of a flow with $n$ nodes, then $S(t) = S_1 s_2 \cdots S_n(t)$ provides a service curve for the entire route of the flow, where $*$ is a convolution operator. The min-plus algebra is an useful tool, so it has been studied for various purposes [9, 15].

On the other hand, a drawback of the deterministic worst-case evaluation is in the overestimation for actually necessary network resources, especially when traffic load is low, the number of flows is large, and the number of nodes is large. It is because the effect of statistical multiplexing is disregarded. To overcome this weak point, a stochastic network calculus has been discussed [1, 4, 5, 6, 14]. Importing statistical evaluation methods to the network calculus, it takes account of the effect of statistical multiplexing. For example, in [6], an advanced calculus is proposed to derive a probabilistic evaluation of the cumulative departures from a given stochastic arrivals and stochastic service curves.

In [13], the authors proposed another new stochastic network calculus by applying a technique used in the large deviations [8]. Large deviations theory and techniques have been used in queueing systems with many flows (see, for example, [3, 10, 12, 17]). In the paper, to derive a new network calculus, the technique is applied to a discrete-time tandem network with $n$ nodes and $L$ flows.

Let $A_i(t,s)$ be the total arrivals to the network during time interval $(s,t]$ and $S_i(t,s)$ the total offered services at node $i$ during $(s,t]$. Given these processes, the cumulative departures from the network $D_i^L(t,s)$ during interval $(s,t]$ and the total backlog in the network $Q_i^L(t,s)$ at time $t$ can be derived. For processes $A_i^L(t,s)$, $S_i^L(t,s)$, $D_i^L(t,s)$ and $Q_i^L(t,s)$, we denote by $\mathcal{A}_i^L(t,s)$, $\mathcal{S}_i^L(t,s)$, $\mathcal{D}_i^L(t,s)$ and $\mathcal{Q}_i^L(t,s)$, respectively, the limits of their cumulant generating functions when $L \to \infty$. In [13], we showed that for a positive $\theta$ in an

ABSTRACT

The stochastic network calculus receives much attention as a new methodology for end-to-end performance evaluation of networks, taking account of the effect of statistical multiplexing. In our previous paper, we proposed a new stochastic network calculus for many flows from an approach like large deviations techniques, and obtained asymptotic end-to-end evaluation formulas for output burstiness and backlog. However, we could not obtain the asymptotic evaluation formula for end-to-end delay in this framework.

In this paper, we enhance the calculation in the previous paper. Concretely we enlarge the domain of the deconvolution operator. Then in addition to for the backlog and the output burstiness in tandem networks, for the delay $V^L(t)$ of $L$ flows at time $t$, using min-plus algebra, we obtain a function of $d > 0$ by which $\limsup_{L \to \infty} L^{-1} \log P(V^L(t) > d)$ are bounded from above. We then discuss an application of the result to a tandem network with cross traffic and give a numerical result.

Figure 1: Tandem network with \( n \) nodes

The cumulative departures from the network during \((0, t] \) is given by

\[ \Theta_C(t) = D_i(t) - D_{i-1}(t) \quad \text{for} \quad i = 2, 3, \ldots, n. \]

This is a little bit simpler expression than before. Using (7)–(9), the relations (2), (5) and (4) are also rewritten as

\[ Q_i(t) = \max_{0 \leq \tau \leq t} \{ A_i(\tau) + S_i(t) - S_i(\tau) \} \]

\[ A_i(t) = \max_{0 \leq \tau \leq t} \{ A_i(\tau) + S_i(t) - S_i(\tau) \} \]

\[ V_i(t) = \min_{0 \leq \tau \leq t} \{ A_i(t - x) - A_i(\tau) \} \]

\[ \Theta_i(t) \leq \Theta_i(t, \tau) - S_i(\tau) \]

respectively. For the cumulative arrivals to the network and the cumulative departures from the network, we introduce

\[ A_1(t) = A_1^{(\text{arr})}(t), \]

\[ Q_i(t) = \max_{0 \leq \tau \leq t} \{ A_i(t) - A_i(\tau) - (S_i(t) - S_i(\tau)) \} \]

\[ D_i(t) = A_i(t) - Q_i(t) \quad \text{and} \]

\[ V_i(t) = \min_{0 \leq \tau \leq t} \{ A_i(t - x) - D_i(t), 0 \leq x \leq t \} \]
similar expressions to (7)–(9) as

\[ \mathbf{A}_{\text{net}}(t, s) = A_{\text{net}}(t) - A_{\text{net}}(s) \quad \text{and} \]
\[ \mathbf{D}_{\text{net}}(t, s) = D_{\text{net}}(t) - D_{\text{net}}(s), \]

and write the total backlogs and the total delay of the network at time \( t \) as

\[ Q_{\text{net}}(t) = A_{\text{net}}(t) - D_{\text{net}}(t), \]
\[ V_{\text{net}}(t) = \min \{ x | \mathbf{A}_{\text{net}}(t - x, t) \leq D_{\text{net}}(t), 0 \leq x \leq t \}. \]

To develop a new network calculus, we introduce operators \( * \) and \( \mathbin{\cap} \) for functions \( f(t, s) \) and \( g(t, s) \) of two variables \( t \) and \( s \), as follows:

\[ f \ast g(t, s) = \min \{ f(t, \tau) + g(\tau, s) \} \quad \text{for} \quad 0 \leq s \leq t, \]
\[ f \mathbin{\cap} g(t, s) = \max \{ f(t, \tau) - g(\tau, s) \} \quad \text{for any} \quad t, s \geq 0. \]

Note that the domains of the two operators are different. We call \( * \) the convolution operator and \( \mathbin{\cap} \) the deconvolution one since these definitions are similar to those of the convolution and deconvolution ones used in [1, 2, 4, 5, 6, 7, 14]. In the previous paper [13], we defined another deconvolution operator on the same domain as the convolution operator. Here, to deal with the delay, we enlarge the domain and this requires some changes in our discussions.

The convolution operator * is associative in the sense that for three functions \( f(t, s) \), \( g(t, s) \) and \( h(t, s) \)

\[ (f \ast g) \ast h(t, s) = f \ast (g \ast h)(t, s). \]

Hence, \( (f \ast g) \ast h(t, s) \) or \( f \ast (g \ast h)(t, s) \) can be written as \( f \ast g \ast h(t, s) \). If the function \( f(t, s) \) has an incremental property, i.e. it is written as \( f(t, s) = f(t, 0) - f(0, s) \) for any \( t, s \geq 0 \), then

\[ f(t, 0) - f(0, s) = f(t, 0) - \min_{0 \leq \tau \leq s} \{ g(s, \tau) + f(\tau, 0) \} = \max_{0 \leq \tau \leq s} \{ f(t, \tau) - g(\tau, s) \} = f \mathbin{\cap} g(t, s). \]

Using these operators, we can rewrite (6), (11), (13) and (10) as

\[ D_i(t) = \mathbf{D}_i(t, 0) = \mathbf{S}_i \ast \mathbf{A}_i(t, 0), \]
\[ Q_i(t) = \mathbf{A}_i \mathbin{\cap} \mathbf{S}_i(t, t), \]
\[ V_i(t) = \min \{ x | \mathbf{A}_i \mathbin{\cap} \mathbf{S}_i(t - x, t) \leq 0, 0 \leq x \leq t \}, \]

and

\[ \mathbf{D}_i(t, s) \leq \mathbf{A}_i \mathbin{\cap} \mathbf{S}_i(t, t), \]

respectively. These equalities and inequality for node \( i \) can be extended to those for the whole network as stated in the following lemma.

**Lemma 1.** For \( t \) and \( s \) such that \( 0 \leq s \leq t \), we have

\[ D_{\text{net}}(t) = \mathbf{D}_{\text{net}}(t, 0) = \mathbf{S}_{\text{net}} \ast \mathbf{A}_{\text{net}}(t, 0), \]
\[ Q_{\text{net}}(t) = \mathbf{A}_{\text{net}} \mathbin{\cap} \mathbf{S}_{\text{net}}(t, t), \]
\[ V_{\text{net}}(t) = \min \{ x | \mathbf{A}_{\text{net}} \mathbin{\cap} \mathbf{S}_{\text{net}}(t - x, t) \leq 0, 0 \leq x \leq t \}, \]

and

\[ D_{\text{net}}(t, s) \leq \mathbf{A}_{\text{net}} \mathbin{\cap} \mathbf{S}_{\text{net}}(t, t), \]

where

\[ \mathbf{S}_{\text{net}}(t, s) = \mathbf{S}_n \ast \mathbf{S}_{n-1} \ast \cdots \ast \mathbf{S}_1(t, s), \]

and

\[ \mathbf{A}_{\text{net}} \mathbin{\cap} \mathbf{S}_{\text{net}}(t, t) = \mathbf{A}_{\text{net}}(t) - \mathbf{D}_{\text{net}}(t, 0). \]

**Proof.** Since \( D_{\text{net}}(t) = D_n(t) \), we have \( D_{\text{net}}(t) = D_{\text{net}}(t, 0) \). On the other hand, from (21) and (12)

\[ \mathbf{D}_i(t, 0) = \mathbf{S}_i \ast \mathbf{A}_i(t, 0) = \mathbf{S}_i \mathbin{\cap} \mathbf{D}_{i-1}(t, 0), \]

Using this relation repeatedly, we have

\[ D_{\text{net}}(t) = \mathbf{D}_{\text{net}}(t, 0) = \mathbf{D}_n(t, 0) = \mathbf{S}_n \ast \mathbf{D}_{n-1}(t, 0) = \cdots \]
\[ = \mathbf{S}_n \ast \mathbf{S}_{n-1} \ast \mathbf{S}_{n-2} \ast \mathbf{D}_1(t, 0) = \cdots \]
\[ = \mathbf{S}_n \ast \mathbf{S}_{n-1} \ast \cdots \ast \mathbf{S}_1 \ast \mathbf{A}_1(t, 0) = \mathbf{S}_{\text{net}} \ast \mathbf{A}_{\text{net}}(t, t). \]

This proves (25). Applying the above representation to (16) and (17), and using relation (20), we have

\[ Q_{\text{net}}(t) = \mathbf{A}_{\text{net}}(t, 0) - \mathbf{D}_{\text{net}}(t, 0) = \mathbf{A}_{\text{net}}(t) - \mathbf{D}_{\text{net}}(0) = \mathbf{A}_{\text{net}} \mathbin{\cap} \mathbf{S}_{\text{net}}(t, t), \]

and

\[ V_{\text{net}}(t) = \min \{ x | \mathbf{A}_{\text{net}}(t - x, t) - \mathbf{S}_{\text{net}} \ast \mathbf{A}_{\text{net}}(t, 0) \leq 0, 0 \leq x \leq t \} \]
\[ = \min \{ x | \mathbf{A}_{\text{net}} \mathbin{\cap} \mathbf{S}_{\text{net}}(t - x, t) \leq 0, 0 \leq x \leq t \}. \]

This proves (26) and (27). Using the inequality \( D_{\text{net}}(t) \leq A_{\text{net}}(t) \) and relations (25) and (20), we have

\[ D_{\text{net}}(t, s) = D_{\text{net}}(t) - D_{\text{net}}(s) \leq A_{\text{net}}(t) - D_{\text{net}}(s) = \mathbf{A}_{\text{net}}(t, 0) - \mathbf{S}_{\text{net}} \ast \mathbf{A}_{\text{net}}(s, 0) \leq \mathbf{A}_{\text{net}} \mathbin{\cap} \mathbf{S}_{\text{net}}(t, s). \]

This proves (28). The representation (30) is a direct consequence of the definition of the convolution operator (18).

From the relation (25), \( \mathbf{S}_{\text{net}}(t, s) \) might be interpreted as the cumulative services through the network offered during \((s, t]\) though it does not have the incremental property, namely \( \mathbf{S}_{\text{net}}(t, s) \neq \mathbf{S}_{\text{net}}(0, 0) - \mathbf{S}_{\text{net}}(s, 0) \), in general.

### 3. Stochastic Network Calculus for Many Flows

We consider the same discrete-time tandem network with \( n \) nodes as in the previous section. In addition, we assume that the traffic through the network consists of \( L \) flows and that arrivals to the network and services at each node are not deterministic but stochastic. For \( t > 0 \), let \( A_i^L(t) \) and \( S_i^L(t) \), \( i = 1, 2, \ldots, n \), be random variables representing the total arrivals to the network and the total services at node \( i \), respectively, during time interval \((0, t]\) for \( L \) flows. Furthermore, let \( D_i^L(t) \) be the total departures from the network of \( L \) flows during \((0, t]\), and \( Q_i^L(t) \) and \( V_i^L(t) \) the total backlog and the total delay of \( L \) flows in the network at time \( t \). Sample paths of the processes \( \{ A_i^L(t) \}, \{ S_i^L(t) \} \),
\{Q^L(t)\}, \{V^L(t)\} and \{D^L(t)\} correspond to \(A^{\text{init}}(t), S(t), Q^{\text{init}}(t), V^{\text{init}}(t)\) and \(D^{\text{init}}(t)\), respectively, in the previous section.

For a pair of times \(t\) and \(s\), we introduce bi-variate functions \(\mathcal{F}^L(t, s)\), \(\mathcal{S}^L(t, s)\) and \(\mathcal{D}^L(t, s)\) as in (14), (8) and (15), namely we let \(\mathcal{F}^L(t, s) = A^L(t) - A^L(s), \mathcal{S}^L(t, s) = S^L(t) - S^L(s)\) and \(\mathcal{D}^L(t, s) = D^L(t) - D^L(s)\). Then from Lemma 1, we have

\[
Q^L(t) = \mathcal{F}^L(t, t),
\]

\[
V^L(t) = \min \{x \mid \mathcal{F}^L(t, t) = 0, 0 \leq x \leq t\}
\]

and

\[
D^L(t, s) \leq \mathcal{F}^L(t, t) \quad \text{with probability one, where}
\]

\[
\mathcal{S}^L(t, s) = \mathcal{S}^L_n + \cdots + \mathcal{S}^L_1(t, s) \quad \text{for} \ 0 \leq s \leq t.
\]

We let

\[
\mathcal{W}^L(t, s) = \mathcal{F}^L(t, t) \quad \text{for} \ 0 \leq s \leq t.
\]

Then (31), (32) and (33) are rewritten as

\[
Q^L(t) = \mathcal{W}^L(t),
\]

\[
V^L(t) = \min \{x \mid \mathcal{W}^L(t, t) = 0, 0 \leq x \leq t\}
\]

and

\[
D^L(t, s) \leq \mathcal{W}^L(t, s).
\]

Note that the random variable \(\mathcal{W}^L(t, t\), \(x\)) is non-increasing as a function of \(x\). Then, if \(\mathcal{W}^L(t, d) > 0\) then all \(x\) satisfying \(\mathcal{W}^L(t, t\), \(x\)) \(0 \leq x \leq t\), is greater than \(d\), namely, \(\mathcal{V}^L(t) > d\). If \(\mathcal{V}^L(t) > d\) then \(\mathcal{W}^L(t, t\), \(d\)) > 0

Hence, for any \(t\) and \(d\) such that \(0 < d < t\), \(\mathcal{V}^L(t) > d\) if and only if \(\mathcal{W}^L(t, t\), \(d\)) > 0. Thus, from (36), (37) and (38), we have the following relations for \(y, d > 0\):

\[
P(Q^L(t) > Ly) = P(\mathcal{W}^L(t, t) > Ly),
\]

\[
P(V^L(t) > d) = P(\mathcal{W}^L(t, t\), \(d\)) > 0, \quad \text{and}
\]

\[
P(\mathcal{D}^L(t, s) > Ly) \leq P(\mathcal{W}^L(t, s) > Ly).
\]

From the definitions (18) and (19) of the convolution and deconvolution operators, \(\mathcal{W}^L(t, s)\) itself is written as

\[
\mathcal{W}^L(t, s) = \max_{0 \leq s_0 \leq t} \{\mathcal{F}^L(t, s_0) - \mathcal{S}^L_n(s_0, s_n-1) - \cdots - \mathcal{S}^L_1(s_1, s_0)\}.
\]

For the sequences of random variables \(\{\mathcal{F}^L(t, s)\}_{L=1,2,\ldots}\) and \(\{\mathcal{S}^L_i(s_i, s_{i-1})\}_{i=1,2,\ldots, n}\), we make the following assumptions. Note that \(\log E[e^{\theta \mathcal{F}}] = \text{cumulant generating function (cgf)} \text{ of random variable } X.

A1. The random variables \(\mathcal{F}^L(t, s)\) and \(\mathcal{S}^L_i(s_i, s_{i-1})\), \(i = 1, \ldots, n\), are mutually independent.

A2. For each \(\theta \in \mathbb{R}\), when \(L \rightarrow \infty\), the sequences

\[
\{L^{-1} \log E[e^{\theta \mathcal{F}^L(t, s_0)}]\}_{L=1,2,\ldots}
\]

and

\[
\{-L^{-1} \log E[e^{-\theta \mathcal{F}^L(s_i, s_{i-1})}]\}_{L=1,2,\ldots}, \quad i = 1, \ldots, n,
\]

have limits as extended real numbers (i.e., allowing ±∞). We denote the limits as

\[
\mathcal{F}^\theta(t, s_0) = \lim_{L \rightarrow \infty} L^{-1} \log E[e^{\theta \mathcal{F}^L(t, s_0)}]
\]

and

\[
\mathcal{S}^\theta(s_i, s_{i-1}) = \lim_{L \rightarrow \infty} L^{-1} \log E[e^{-\theta \mathcal{F}^L(s_i, s_{i-1})}], \quad i = 1, \ldots, n.
\]

A3. The sets \(\mathcal{Z}_{\mathcal{F}^\theta}(t, s_0) \equiv \{\theta : \mathcal{F}^\theta(t, s_0) < \infty\} \cap (0, \infty)\) and \(\mathcal{Z}_{\mathcal{S}^\theta(s_i, s_{i-1})} \equiv \{\theta : \mathcal{S}^\theta(s_i, s_{i-1}) < \infty\} \cap (0, \infty), i = 1, \ldots, n\), are all non-empty.

From the monotonicity of the logarithmic and exponential functions, it is easily checked that the set \(\mathcal{Z}_{\mathcal{F}^\theta}(t, s_0)\) is an open or semi-closed interval of the form \((0, \delta_{\mathcal{F}^\theta}(t, s_0))\) or \((0, \delta_{\mathcal{S}^\theta(s_i, s_{i-1})})\) with some positive number \(\delta_{\mathcal{F}^\theta(t, s_0)}\) or with \(\delta_{\mathcal{S}^\theta(s_i, s_{i-1})} = \infty\). The set \(\mathcal{Z}_{\mathcal{S}^\theta(s_i, s_{i-1})}\) is also such an interval. Hence, under assumptions A2 and A3, the intersection

\[
\mathcal{Z}_{\mathcal{F}^\theta(t, s_0)} \cap \mathcal{Z}_{\mathcal{S}^\theta(s_i, s_{i-1})} = \mathcal{Z}_{\mathcal{F}^\theta(t, s_0)} \cap \mathcal{Z}_{\mathcal{S}^\theta(s_i, s_{i-1})} = \mathcal{Z}_{\mathcal{F}^\theta(s_i, s_{i-1})}, \quad i = 1, \ldots, n
\]

is a non-empty interval, too.

We have the following lemma.

**Lemma 2.** Under assumptions A1, A2 and A3, the sequence

\[
\{L^{-1} \log E[e^{\theta \mathcal{W}^L(t, s_0)}]\}_{L=1,2,\ldots}
\]

with \(\theta \in \mathcal{Z}_{\mathcal{F}^\theta(t, s_0)}\) has a finite limit \(\mathcal{W}^\theta(t, s_0)\) as \(L \rightarrow \infty\), and the limit is given by

\[
\mathcal{W}^\theta(t, s) = \mathcal{F}^\theta \otimes \mathcal{S}^\theta(t, s),
\]

\[
= \max_{0 \leq s_0 \leq s_1 \leq \cdots \leq s_n} \{\mathcal{F}^\theta(t, s_0) - \mathcal{S}^\theta_n(s_n, s_{n-1}) - \cdots - \mathcal{S}^\theta_1(s_1, s_0)\}
\]

where

\[
\mathcal{S}^\theta(s) = \mathcal{S}^\theta_n \ast \cdots \ast \mathcal{S}^\theta_1(t, s).
\]

**Proof.** First we show that, when \(L \rightarrow \infty\), the superior limit of \(L^{-1} \log E[e^{\theta \mathcal{W}^L(t, s_0)}]\) is bounded from above by the right hand side of (47) and the inferior limit of it is bounded from below by the same quantity.
Since $\theta > 0$, from (42), using the monotonicity of the exponential function and the inequality $\max(x_1, x_2) \leq x_1 + x_2$ for $x_1, x_2 \geq 0$, we have
\[
e^{-\theta L(t,s)} = \max_{0 \leq s_0 \leq \cdots \leq s_n = s} e^{\theta \sum_{i=0}^{n} S_i^0((s_i, s_{i-1}) - S_1^0((s_1, s_0)))} \leq \sum_{0 \leq s_0 \leq \cdots \leq s_n = s} e^{\theta \sum_{i=0}^{n} S_i^0((s_i, s_{i-1}) - S_1^0((s_1, s_0)))}
\]
with probability one. Taking expectation on both sides,
\[
E[e^{-\theta L(t,s)}] \leq \sum_{0 \leq s_0 \leq \cdots \leq s_n = s} E[e^{\theta \sum_{i=0}^{n} S_i^0((s_i, s_{i-1}) - S_1^0((s_1, s_0)))}]
\]

From assumption A1, the expectation in the right hand side above can be written in a product form
\[
E[e^{\theta L(t,s)}] = E[e^{-\theta S_0^0((s_0, s_{-1}) - S_1^0((s_1, s_0)))}] \cdots E[e^{-\theta S_n^0((s_n, s_{n-1}) - S_1^0((s_1, s_0)))}].
\]

Then using the monotonicity of the logarithmic function, the above inequality is rewritten as
\[
L^{-1} \log E[\mathcal{P}_L(t,s)] \leq \sum_{0 \leq s_0 \leq \cdots \leq s_n = s} \{L^{-1} \log E[e^{\theta \sum_{i=0}^{n} S_i^0((s_i, s_{i-1}) - S_1^0((s_1, s_0)))}]
\]

If we let $L \to \infty$, from assumptions A2 and A3, each term in the braces above converges to a finite limit. Hence by taking superior limit on both sides we have
\[
\limsup_{L \to \infty} L^{-1} \log E[\mathcal{P}_L(t,s)] \leq \sum_{0 \leq s_0 \leq \cdots \leq s_n = s} \{\mathcal{P}_L(t, s_0) - S_1^0((s_1, s_0))\}.
\]

On the other hand, from (42), for arbitrarily chosen $(s_0, s_1, \cdots, s_n)$, we have
\[
\mathcal{P}_L(t, s_0) \geq \mathcal{P}_L(t, s_0) - S_1^0((s_1, s_0))\] with probability one. Then for $\theta \in \mathcal{Z}_{\mathcal{P}_L(t,s)}$, we have
\[
E[e^{\theta \mathcal{P}_L(t,s)}] \geq E[e^{\theta \sum_{i=0}^{n} S_i^0((s_i, s_{i-1}) - S_1^0((s_1, s_0)))}].
\]

From assumption A1, the right hand side is written in a product form. Then, taking logarithm and dividing by $L$ we have
\[
L^{-1} \log E[\mathcal{P}_L(t,s)] \geq L^{-1} \log E[e^{\theta \mathcal{P}_L(t,s)}] + L^{-1} \log E[e^{-\theta S_0^0((s_0, s_{-1}) - S_1^0((s_1, s_0)))}] \cdots + L^{-1} \log E[e^{-\theta S_n^0((s_n, s_{n-1}) - S_1^0((s_1, s_0)))}].
\]

As $L \to \infty$, from assumptions A2 and A3, each term in the right hand side converges to a finite limit. Then by taking inferior limit on both sides, we have
\[
\liminf_{L \to \infty} L^{-1} \log E[e^{\theta \mathcal{P}_L(t,s)}] \geq \mathcal{P}_L(t, s_0) - S_1^0((s_1, s_0)) - \cdots - S_1^0((s_1, s_0)).
\]

Since the inequality holds for any choice of $(s_0, s_1, \cdots, s_n)$, we have
\[
\liminf_{L \to \infty} L^{-1} \log E[e^{\theta \mathcal{P}_L(t,s)}] \geq \mathcal{P}_L(t, s_0) - S_1^0((s_1, s_0)) - \cdots - S_1^0((s_1, s_0)).
\]

Thus, both the superior limit and the inferior limit of $L^{-1} \log E[e^{\theta \mathcal{P}_L(t,s)}]$ are bounded by the right hand side of (47). This proves (47). The representation (46) is led from (47) in the reverse way of (42).

\begin{theorem}
Under assumptions A1, A2 and A3 for $s = t > 0$, we have, for $y > 0$,
\[
\limsup_{L \to \infty} L^{-1} \log P(\mathcal{P}_L(t,t) > L y) \leq \inf_{\theta \in \mathcal{Z}_{\mathcal{P}_L(t,t)}} \{ -\theta y + \mathcal{Q}_L \}.
\]

Under assumptions A1, A2 and A3 for $0 < d \leq t$, we have
\[
\limsup_{L \to \infty} L^{-1} \log P(\mathcal{P}_L(t,t) > d) \leq \inf_{\theta \in \mathcal{Z}_{\mathcal{P}_L(t-d,t)}} \{ -\theta y + \mathcal{Q}_L \}.
\]

Under assumptions A1, A2 and A3 for $0 < s \leq t$, we have, for $y > 0$,
\[
\limsup_{L \to \infty} L^{-1} \log P(\mathcal{P}_L(t,s) > L y) \leq \inf_{\theta \in \mathcal{Z}_{\mathcal{P}_L(t,s)}} \{ -\theta y + \mathcal{Q}_L \}.
\]

Proof. We apply the Chernoff’s bound (or the Markov inequality, see p.240 of [5]) to the tail probability $P(\mathcal{P}_L(t,s) > L y)$. For any $\theta \in \mathcal{Z}_{\mathcal{P}_L(t,s)}$ and $y \geq 0$, we have
\[
P(\mathcal{P}_L(t,s) > L y) = P(e^{\theta \mathcal{P}_L(t,s)} > e^{\theta L y}) \leq e^{-\theta L y} E[\mathcal{P}_L(t,s)].
\]

Taking the logarithm, dividing by $L$, and then taking the superior limit on both sides, we have
\[
\limsup_{L \to \infty} L^{-1} \log P(\mathcal{P}_L(t,s) > L y) \leq -\theta y + \mathcal{Q}_L(t,s).
\]

Since the parameter $\theta$ does not appear in the left hand side, it follows that
\[
\limsup_{L \to \infty} L^{-1} \log P(\mathcal{P}_L(t,s) > L y) \leq \inf_{\theta \in \mathcal{Z}_{\mathcal{P}_L(t,s)}} \{ -\theta y + \mathcal{Q}_L(t,s) \}.
\]

We know that $P(\mathcal{P}_L(t,t) > L y) = P(\mathcal{P}_L(t,t) > L y)$ and $P(\mathcal{P}_L(t,t) > d) = P(\mathcal{P}_L(t-d,t) > 0)$ from (39) and (40). Hence, if considering the case of $\mathcal{P}_L(t,t)$, the inequality (52) proves (49), and if considering the case of $\mathcal{P}_L(t-d,t)$ and $y = 0$, the inequality (52) proves (50). Similarly, from (41) we see that $P(\mathcal{P}_L(t,s) > L y) \leq P(\mathcal{P}_L(t,s) > L y)$. Hence the inequality (52) also implies (51).
\end{theorem}
Theorem 1 suggests that the tail probabilities of \( Q^L(t) \), \( V^L(t) \) and \( L^t \) might be evaluated by the form
\[
P(Q^L(t) > L y) \leq B_Q(L, y) \exp \left( L \inf_{y \in A(t)} \left\{ -\theta y + \mathcal{W}'(t) \right\} \right),
\]
and
\[
P(V^L(t) > d) \leq B_v(L, d) \exp \left( L \inf_{d \in A(t)} \left\{ -\theta y + \mathcal{W}'(t - d, t) \right\} \right)
\]
where \( B_D(L, y), B_v(L, d) \) are some functions varying slower than the exponential as \( L \) increases.

4. APPLICATION TO A NETWORK WITH CROSS TRAFFIC

![Figure 2: Tandem network with cross traffic](image)

We apply the bound (54) to a network with cross traffic depicted in Figure 2. In the network, there are \( L \) forwarding flows and \( M_i \) cross traffic flows at node \( i \). We denote the \( L \) forwarding flows as \( \{A_1(t)\}, \{A_2(t)\}, \ldots, \{A_L(t)\} \) and the \( M_i \) cross traffic flows at node \( i \) as \( \{A_{M_i^{\text{cross}}}(t)\}, \{A_{M_2^{\text{cross}}}(t)\}, \ldots, \{A_{M_i^{\text{cross}}}(t)\} \). We set \( \alpha_i = M_i/L \), the ratio of the number of the cross traffic flows at node \( i \) to that of the forwarding traffic flows, and is kept constant when we move \( L \) (and \( M_i \)) to infinity later. The link capacity, i.e., the offered service per unit time, at node \( i \) is constant and equal to \( C_i = \beta_i L \). When we move \( L \) later, \( \beta_i \) is kept constant. At the service, the cross traffic is served with higher priority than the forwarding traffic.

Here, for brevity of the model, we assume that flows (both forwarding flows and cross traffic flows) are mutually independent and subjecting to a common probabilistic law. We denote by \( A(t) \) the arrival process of a typical flow, and make the following assumptions.

C1. The arrival process \( \{A(t)\} \) is nondecreasing and has stationary increments with probability one.

C2. The arrival process \( \{A(t)\} \) is a greedy process which is limited by a leaky bucket, namely, the cgf \( A(t) = \log E[e^{\theta A(t)}] \) of \( A(t) \) is given by
\[
\eta^t(t, \theta) \equiv \log \left[ 1 + \frac{\rho t}{\mu t + \sigma} (e^{\theta \rho t + \sigma} - 1) \right],
\]
where \( \rho \) is the average flow rate and \( \sigma \) is the burst size.

If the arrival process \( \{A(t)\} \) is just limited by a leaky bucket, namely, \( A(t) = A(t) - A(s) \leq \rho(t - s) + \sigma \) holds with probability one for any \( t, s \) such that \( 0 \leq s \leq t \), then the cgf \( A(t) \) of \( \{A(t)\} \) satisfies the inequality \( A(t) \leq \eta^t(t, \theta) \) from [11]. The assumption C2 is that the equation \( A(t) = \eta^t(t, \theta) \) holds.

Under assumptions C1 and C2, the cgf \( \mathcal{X}(t, s) \) of \( \{A(t, s)\} \) is given as
\[
\mathcal{X}(t, s) = \eta(t - s) \quad \text{for} \quad \theta \in (0, \infty),
\]
where
\[
\eta(t) = \left\{ \begin{array}{ll}
\eta^t(t, \theta) & \text{if } t > 0 \\
0 & \text{if } t = 0 \\
-\eta^t(-t, \theta) & \text{if } t < 0.
\end{array} \right.
\]
The function \( \eta^t(t, \theta) \) is concave on \( t \) for each fixed \( \theta \) and convex on \( \theta \) for each fixed \( t \) (see Appendix).

In this network model, the cumulative arrivals to the network is given by the sum of cumulative arrivals of the \( L \) forwarding traffic flows, \( A^M(t) = A_1(t) + A_2(t) + \cdots + A_L(t) \), and the cumulative services at node \( i \) for the forwarding traffic is given by
\[
S_i^L(t) = \max_{0 \leq r \leq t} \left\{ C_i \tau - A_i^M(t) - C_i(t - \tau) \right\}, \quad (59)
\]
where \( A_i^M(t) \) is the cumulative arrivals of the cross traffic flows in node \( i \) at time \( t \), i.e., \( A_i^M(t) = A_i^{M_{\text{cross}}}(t) + A_i^{M_{\text{cross}}}(t) + \cdots + A_i^{M_{\text{cross}}}(t) \). The representation (59) is derived from the relation
\[
S_i^L(t) = C_i t - \left\{ A_i^{M_{\text{cross}}}(t) - Q_i^{M_{\text{cross}}}(t) \right\}
\]
where \( Q_i^{M_{\text{cross}}}(t) \) is the backlog \( Q_i^{M_{\text{cross}}}(t) \) of the cross traffic in node \( i \) at time \( t \), which is given, analogously to (2), by
\[
Q_i^{M_{\text{cross}}}(t) = \max_{0 \leq r \leq t} \left\{ A_i^{M_{\text{cross}}}(t) - A_i^{M_{\text{cross}}}(t) - C_i(t - \tau) \right\}.
\]
We denote the increment of arrivals in forwarding traffic as \( \mathcal{X}(t, s) = \mathcal{X}(t) - \mathcal{X}(s) \). Then its cgf is given by \( L \) times of \( \mathcal{X}(t, s) \), i.e. \( L \mathcal{X}(t, s) \), since \( L \) flows \( \{A_1(t)\}, \{A_2(t)\}, \ldots, \{A_L(t)\} \) are mutually independent and subjecting to a common probabilistic law. So the limit (43) is also given by \( \mathcal{X}(t, s) \).

Similarly, we denote the increment of arrivals in the cross traffic during \( (s, t) \) at node \( i \) as \( \mathcal{X}_i^{M_{\text{cross}}}(t) = A_i^{M_{\text{cross}}}(t) - A_i^{M_{\text{cross}}}(s) \). Then its cgf is given by \( M_i \mathcal{X}(t, s) \).

Hence, the function \( \mathcal{X}_i^{M_{\text{cross}}}(t, s) = \lim_{L \to \infty} L^{-1} \{ M_i \mathcal{X}(t, s) \} \) is given by \( \mathcal{X}_i^{M_{\text{cross}}}(t, s) = \alpha_i \mathcal{X}(t, s) \), and then
\[
\mathcal{X}_i^{M_{\text{cross}}}(t, s) = \alpha_i \eta(t - s, \theta) \quad \text{for} \quad \theta \in (0, \infty).
\]
From (59), the increment of services \( \tilde{S}_i^L(t, s) = S_i^L(t) - S_i^L(s) \) during \( (s, t) \) at node \( i \) is given by
\[
\tilde{S}_i^L(t, s) = \max_{0 \leq r \leq t} \left\{ C_i \tau - A_i^{M_{\text{cross}}}(t) \right\} - \max_{0 \leq r \leq t} \left\{ C_i \tau - A_i^{M_{\text{cross}}}(s) \right\}.
\]
From the independence assumption of input flows and the equations (57) and (60), we can easily see that assumptions...
A1, A2 and A3 are satisfied with \( Z_{\mathcal{T}(t,s_0)} = (0, \infty) \) and \( Z_{\mathcal{T}(t,s_{n-1})} = (0, \infty) \). Hence the results of the preceding section can be applied with \( Z_{\mathcal{T}(t,s)} = (0, \infty) \).

However, the function \( \tilde{S}_i^L(t,s) \) in (61) seems too complicated to evaluate \( \tilde{W}^i(t-d,t) \) in (54), because two maximization operations prevent us from calculating its cdf. Here we introduce two alternatives.

\[
\tilde{S}_i^L(t,s) = \max_{0 \leq s \leq L} \left\{ C_i(t,s) - \mathcal{M}_i^{\text{cross}}(t,s) \right\} \quad \text{and} \quad (62)
\]

\[
\tilde{S}_i^H(t,s) = \left[ C_i(t,s) - \mathcal{M}_i^{\text{cross}}(t,s) \right]^+, \quad (63)
\]

where \([x]^+ = \max\{0,x\}\). Unfortunately, they do not satisfy the incremental property. So they are difficult to understand as increments of some single functions representing cumulative services. However, the function \( \tilde{S}_i^L(t,s) \) provides the same function \( \tilde{W}^i(t,s) \) as \( \tilde{S}_i^L(t,s) \) as shown below, and the function \( \tilde{S}_i^H(t,s) \), which is naturally led from \( \tilde{S}_i^L(t,s) \), provides a calculable substitute for \( \tilde{W}^i(t,s) \). Their properties stated below will be proved in Appendix.

The three functions \( \tilde{S}_i^L(t,s) \), \( \tilde{S}_i^H(t,s) \) and \( \tilde{S}_i^L(t,s) \) satisfy the inequalities

\[
\tilde{S}_i^L(t,s) \leq \tilde{S}_i^L(t,s) \quad \text{and} \quad \tilde{S}_i^H(t,s) \geq \tilde{S}_i^L(t,s) \quad (64)
\]

with probability one (see Appendix), and by taking a convolution with \( \tilde{A}_i(t,s) \) they can represent the cumulative departures \( \tilde{D}_i(t) \) at node \( i \) as

\[
\tilde{D}_i^L(t) = \tilde{S}_i^L(t,s) \quad \text{and} \quad (65)
\]

\[
\tilde{D}_i^H(t) = \tilde{S}_i^H(t,s) \quad \text{as usual.}
\]

Using these properties we easily see that

\[
\tilde{W}^L_i(t,s) = \tilde{A}_i^L(t,s) \quad \text{and} \quad (66)
\]

\[
\tilde{W}^H_i(t,s) = \tilde{A}_i^H(t,s) \quad \text{as usual.}
\]

(see Appendix), where \( \tilde{S}_i^L(t,s) = \tilde{A}_i^L(t,s) \). The convex function \( \varphi_i(t,s) \), the maximum in the maximization of (70) can be numerically calculated by an iteration using a usual numerical technique such as the bisection method or the Newton method. On the other hand, for given \( t, s_0, \ldots, s_n = s \), the function to be taken infimum on \( \theta \) is not convex, in general, because of the existence of operations \([x]^+\). So, there might exist multiple local minima. However, the number of such local minima is at most \( 2n \). So, it is very difficult to find infimum numerically.

Consider the special case where \( n \) nodes are homogeneous and \( \alpha_0 \) and \( \beta_0 \) are common, namely \( \beta_i = \beta \) and \( \alpha_i = \alpha \) for \( i = 1, 2, \ldots, n \). From the convexity of \( \varphi_i(t) \), the maximum in (70) is attained by \( s_0, s_1, \ldots, s_n = s \) such that

\[
s_1 - s_0 = s_2 - s_1 = \cdots = s_n - s_{n-1} = \frac{s - s_0}{n}.
\]

Hence the right hand side of (70) is reduced to

\[
\inf_{\theta \in (0, \infty)} \left\{ -\theta y + \max_{0 \leq s \leq L} \left\{ \eta(t,s_0,\theta) \right\} \right\} \quad (71)
\]

This inf-max problem can be easily solved numerically by using a usual numerical technique.

When we evaluate the total delay by \( (50) \) and (67), the above formula is further reduced to

\[
\inf_{\theta \in (0, \infty)} \max_{0 \leq s \leq L} \left\{ \eta(t - d - s_0,\theta) \right\} \quad (72)
\]
A numerical example: Now we apply the inequality (54) to a specific case of the network depicted in Figure 2. We consider a homogeneous case where the parameters are set as $n = 3$, $L = 10$, $L\alpha = 50$, $L\beta = 2.5$Gbps, $\rho = 40$Mbps and $\sigma = 4$Mbits. The link utilization in each node is 96% ($(((10 + 50) \times 40 \times 10^6)/(2.5 \times 10^9)) = 0.96$). The time $t$ of $P(V(t) > d)$ is chosen to be sufficiently large so that $P(V(t) > d)$ indicates a stationary probability.

Figure 3 shows a numerical result calculating the exponential part of (54). The ordinate is the logarithm of (54) to base 10 and the abscissa is the delay threshold $d$. The three curves with letters “1 node”, “2 nodes” and “3 nodes” attached correspond to the delay distribution through one node, that through two nodes and that through three nodes, respectively. The three perpendicular broken lines show the maximum delays for $i$ nodes, $i = 1, 2, 3$ under the restriction by a leaky bucket.

In practical applications, the evaluation (54) may not be accurate in two reasons. The first is, as is usually seen in asymptotic evaluations, that the coefficient function $B_3(L, y)$ is not known. We only know the exponential part. The second is that our model uses the greedy process which is limited by a leaky bucket as the input process. Usually, it is only known that the input process is limited by the leaky bucket, and the input process is not identified. So, the new findings we can obtain from the numerical results are somehow limited. However, at least, we can point out the following facts. In the greedy input case, the maximum delay increases as the number of nodes increases, but the upper bound of the probability $P(V(t) > d)$ decreases faster than the exponential as the delay threshold $d$ increases in spite of the high link utilization of 96%.

5. REFERENCES

APPENDIX

Here we give a proof for the concavity of the function $\eta^+(t, \theta)$ given in (56) and proofs for the properties (64), (65), (66) and (67) of the functions $S_L^L(t, s)$ and $S_L^L(t, s)$ presented in Section 4. For brevity of notation, we set $\xi_i(t) = \beta_i LT - A_i^{L, \text{cos}}(t)$ and $\xi_i(t_1, t_2) = \xi(t_1) - \xi(t_2)$.

Proof of the concavity of $\eta^+(t, \theta)$ in (56): The function $\eta^+(t, \theta)$ is rewritten as

$$\eta^+(t, \theta) = \theta (pt + \sigma) - \log [pt + \sigma] + \log \left[ pt + \sigma e^{-\theta (pt + \sigma)} \right].$$

Then it is easily checked that $\eta^+(0, \theta) = 0$ and $\lim_{x \to \infty} \{ \eta^+(t, \theta) - \theta (pt + \sigma) \} = 0$. So, roughly speaking, the func-
tion \eta^+(t, \theta) grows along a straight line \theta(\rho t + \sigma) as \( t \to \infty \). Its first and second derivatives on \( t \) are given as

\[
\frac{\partial}{\partial t} \eta^+(t, \theta) = \theta \rho - \frac{\rho}{\rho t + \sigma} + \rho - \theta \rho e^{-(\rho t + \sigma)}, \quad \text{and}
\]

\[
\frac{\partial^2}{\partial t^2} \eta^+(t, \theta) = -\frac{\rho^2}{(\rho t + \sigma)^2} e^{-(\rho t + \sigma)} \left[ 1 - 2\theta(\rho t + \sigma)e^{-(\rho t + \sigma)} - e^{-2\theta(\rho t + \sigma)} \right]
\]

\[
+ 2\rho \eta(t) \left[ 1 - e^{-\theta(\rho t + \sigma)} - \theta(\rho t + \sigma)e^{-(\rho t + \sigma)} \right]
\]

\[
- \frac{1}{2} \frac{\partial^2}{\partial \theta^2} e^{-(\rho t + \sigma)} \].
\]

It is easily checked that the first derivative is positive and the second derivative is negative for \( t > 0 \), because \( h_1(x) \equiv 1 - 2xe^{-x} - e^{-2x} + 0 > 0 \) and \( h_2(x) \equiv x^2 - 1 - x - \frac{1}{4}x^2 > 0 \) for \( x > 0 \). Hence, as a function of \( t, \eta(t, \theta) \) is increasing and concave. On the other hand, the first derivative on \( \theta \) is given by

\[
\frac{\partial}{\partial \theta} \eta^+(t, \theta) = \frac{\rho t(\rho t + \sigma)}{\rho t + \sigma} e^{-(\rho t + \sigma)}.
\]

It is positive and increasing. Hence, as a function of \( \theta, \eta^+(t, \theta) \) is increasing and convex.

**Proof of (64):** The first inequality of (64) is proved as follows.

\[
S_i^1(t, s) = \max_{0 \leq \tau_1 \leq t} \xi(t_1) - \max_{0 \leq \tau_2 \leq s} \xi(t_2)
\]

\[
= \max \left\{ \max_{0 \leq \tau_1 \leq t} \xi(t_1), \max_{s \leq \tau_1 \leq t} \xi(t_1) \right\} - \max_{0 \leq \tau_2 \leq s} \xi(t_2)
\]

\[
= \max \left\{ 0, s \leq \tau_1 \leq s \right\} - \max_{0 \leq \tau_2 \leq s} \xi(t_2)
\]

\[
\leq \max \left\{ 0, s \leq \tau_1 \leq s \right\} - \xi(s)
\]

\[
= \max_{s \leq \tau_1 \leq t} \xi(t, s) = S_i^1(t, s).
\]

Considering the cases \( \tau = s \) and \( \tau = t \) in the right hand side of (62), we have the inequality

\[
S_i^1(t, s) \geq \max \left\{ 0, \xi(s) \right\} = S_i^1(t, s).
\]

This proves the second inequality of (64).

**Proof of (65):** The second equality in (65) is proved as follows. From (21) and (61),

\[
D_i^0(t) = S_i^1(t, 0) = \min_{0 \leq \xi \leq s} \left\{ A_i^0(s) + S_i^1(t, s) \right\}
\]

\[
= \min_{0 \leq \xi \leq s} \left\{ A_i^0(s) + \max_{0 \leq \tau_1 \leq t} \xi(t_1) - \max_{0 \leq \tau_2 \leq s} \xi(t_2) \right\}
\]

\[
= \min_{0 \leq \xi \leq s} \left\{ \max_{0 \leq \tau_1 \leq t} \xi(t_1) + \max_{0 \leq \tau_2 \leq s} \xi(t_2) \right\} - \max_{0 \leq \tau_2 \leq s} \xi(t_2)
\]

\[
= \max_{0 \leq \xi \leq s} \left\{ -A_i^0(s) + \xi(t_1) \right\}
\]

\[
= \max_{0 \leq \xi \leq s} \left\{ -A_i^0(s) + \xi(t_1) \right\} \quad \text{since } A_i^0(t_2) \leq A_i^0(s) \text{ for } t_2 \leq s.
\]

Let \( \tau_i^\ast \) be the value of \( \tau_i \) which attains the maximum in the first term, and \( \tau_i^\ast \) be the minimum value of \( \tau_i \) which attains the maximum in the second term. Then we can show that \( \tau_i^\ast \leq \tau_i^\ast \). Because, if contrary, i.e. \( \tau_i^\ast > \tau_i^\ast \), then \( A_i^0(\tau_i^\ast) \geq A_i^0(\tau_i^\ast) \), and hence

\[
- A_i^0(\tau_i^\ast) + \xi(\tau_i^\ast) \geq - A_i^0(\tau_i^\ast) + \xi(\tau_i^\ast) \geq - A_i^0(\tau_i^\ast) + \xi(\tau_i^\ast) \).
\]

The first inequality comes from the definition of \( \tau_i^\ast \) and the second inequality comes from the definition of \( \tau_i^\ast \). These inequalities imply that \( \tau_i^\ast = \tau_i^\ast \) (or \( \tau_i^\ast \)) also attains the maximum in the second term of (73), and it contradicts with the minimum assumption of \( \tau_i^\ast \). Then (73) can be rewritten as

\[
D_i^0(t) = \min_{0 \leq \tau_2 \leq s} \left\{ \max_{\tau_2 \leq t} \xi(t_1) + A_i^0(\tau_2) - \xi(t_2) \right\}
\]

\[
= \min_{0 \leq \tau_2 \leq t} \left\{ A_i^0(\tau_2) + \max_{\tau_2 \leq t} \xi(t_1, \tau_2) \right\}
\]

\[
= \min_{0 \leq \tau_2 \leq t} \left\{ A_i^0(\tau_2) + S_i^1(t_1, \tau_2) = S_i^0(t_1, t, 0). \right\}
\]

This proves the second equality in (65).

The inequality in (65) is derived from the second inequality of (64) and the property of the convolution operator.

**Proof of (66) and (67):** We denote the increment of cumulative departures during \( (s, t) \) at node \( i \) as \( D_i^0(t, 0) = D_i^0(t) - D_i^0(s), \) as usual. Using the second equality \( D_i^0(t, 0) = S_i^0(t, 0) + S_i^2(t, 0), \) in (65) repeatedly, we can show that \( D_i^0(t) = S_i^2(t, 0) + S_i^2(t, 0) \) as in the proof of (25) in Lemma 1. Since \( D_i^0(t) = S_i^2(t, 0), \) we see that \( S_i^2(t, 0) = S_i^2(t, 0), \) hence from the relation (20),

\[
W(t, s) = \bar{T}^0 \circ S_i^2(t, s) = \bar{T}^0(t_1, 0) - S_i^2(t_1, s) = \bar{T}^0(t_1, 0) - \bar{T}^0(t_1, s) = \bar{T}^0(t_1, s).
\]

This proves the equality of (66).

Similarly, using the inequality \( D_i^0(t) \geq S_i^2(t, 0) \) in (65) repeatedly, we can show that \( D_i^0(t) \geq S_i^2(t, 0) \). Hence, \( \bar{T}^0 \circ S_i^2(t_1, 0) = \bar{T}^0(t_1, 0) \). Then from the relation (20),

\[
W(t, s) = \bar{T}^0 \circ S_i^2(t, s) = \bar{T}^0(t_1, 0) - S_i^2(t_1, s) = \bar{T}^0(t_1, 0) - \bar{T}^0(t_1, s) = \bar{T}^0(t_1, s).
\]

This proves the inequality of (66).

**Proof of (68):** The representation (68) is derived as follows.

\[
\tilde{S}^0(t, s) = -\lim_{L \to \infty} L^{-1} \log E\left[ e^{-\theta \bar{T}^0(t_1, s)} \right]
\]

\[
= -\lim_{L \to \infty} L^{-1} \log E\left[ e^{-\theta \bar{T}^0(t_1, s)} \right] \]

\[
\geq \left\{ 0, -\lim_{L \to \infty} L^{-1} \log E\left[ e^{-\theta \bar{T}^0(t_1, s)} \right] \right\}
\]

\[
= \left\{ 0, -\lim_{L \to \infty} L^{-1} \log E\left[ e^{-\theta \bar{T}^0(t_1, s)} \right] \right\}.
\]
